PART I: Analysis

1 Problem Definition and Data Requirements

1.1 Problem Description

Any successful business owner knows that to run a successful business, one must have a database management system that stores all needed data when analysing, improving, and maintaining the profits and contracts. While managing records concerning branches, employees, and departments. Making sure that clients are satisfied with the given services that the business provides them with.

That is why when the owner of Smash Up GYM contacted us to design a database to help him organize the GYM's management system, increase, or maintain its profits, we made sure to design a database that satisfies his requirements in keeping records about the employees, members, health records, contracts, lockers, and equipment. Organizing stored data about the branches, departments, classes, membership plans, and events.

The system will also help in linking the branch's information together. It will help in making accurate and precise estimations about the total net profits. It will also help in making decisions about the branches and membership plans. Our goal for Smash Up GYM is to design a comprehensive database, as well as make it easy to deal with in a highly efficient manner, to meet the owner's requirements.

1.2 Data Requirements

1. **Employees:**

   An employee would have the following data:

   - Employee ID
   - Name (First name, Middle name, Last name)
   - Phone number
   - Date of birth (Day, Month, Year)
   - Age
   - Address (City, Street, Building number)
   - Gender (F/M)
   - Bank account
   - Salary

2. **Members:**

   Members of the GYM must have the following information stored in the system:

   - Member ID
   - Name (First name, Middle name, Last name)
   - Date of birth (Day, Month, Year)
   - Age
   - Gender (F/M)
   - Social state (Single/Married)
   - Phone number
   - Email

3. **Branches:**

   All branches must have the following data stored in the system:

   - Branch No
   - Address (City, Street, Building number)
   - Phone number
   - Working hours (Opening hour, Closing hour)
   - Branch's capacity
   - Number of members
   - Number of employees

4. **Departments:**

   Each department will have:

   - Department number
   - Name (Maintenance, Customer service, Management, Medical care, Coaching staff)
   - Number of employees

5. **Classes:**

   To organize the classes, each class must have the following data stored:

   - Class reference number
   - Place (Days, Hours, Room No)
   - Activity

6. **Lockers:**

   All lockers will have the following information:

   - Locker No
   - Password
   - State (Occupied/Available)

7. **Membership plans:**

   All membership plans that the GYM offers will have:

   - Membership plan ID
   - Plan's name (Diamond/Golden/Platinum)
   - Services {Personalized meal plan, Massage sessions, Personal trainer, Nursery}
   - Duration (3 months/6 months/12 months)
   - Price

8. **Sports Equipment:**

   An equipment in the GYM will have the following data:

   - Machine No
   - Name
   - State (Out of service / In service)

9. Events:

Any event that is hosted by the GYM must have:

- Event's name
- Start date (Day, Month, Year)
- Duration (Number of Days, Number of Hours per day)
- Location (City, Hosting place name)

10. Health records:

The health records of every member will be stored in the database as the following:

- Date of record
- Height
- Weight
- Blood type
- Blood pressure
- Body fat
- BMI
- Body water
- Body mass
- Muscle mass

11. Contracts:

To maintain all contracts, the following data must be stored:

- Contract ID
- Start date (Day, Month, Year)
- End date (Day, Month, Year)
- Date of payment (Day, Month, Year)
- Payment method (Cash/Credit card)
- Applied discounts
- Applied taxes

1.3 Business Rules

To manage the GYM's business efficiently without any conflicts, there are some rules, specified and stated by the owner, that we must take into consideration whilst designing the database.

1. **Employees**

   Each employee's contact information and bank account must be stored.

2. **Members**

   A member must be at least 16 years old to apply to the GYM.

3. **Branches**

   Depending on the branch's location, each branch will have different working hours. Overall working hours of a branch should be at least 12 hours.

4. **Departments**

   The department's number and name should be stored.

5. **Classes**

   To organize classes information and distinguish them, each class must have a reference number. To prevent overlapping, no two classes can occur at the same time, at the same room.

6. **Lockers**

   To determine the locker's availability, each locker's state must be recorded.
   The locker's number, password, and owner's ID must be saved.

7. **Membership plans**

   All plans must have distinct IDs. The services, duration, and price of plans must be stored.

   For example, the Golden plan with the duration of 3 months will have a distinct ID than the Golden plan with 6 months duration. Same goes for Diamond, and Platinum plan.

8. **Sports Equipment**

   Each device will have a unique number to distinguish it. The device's state and location must be recorded, in case of an equipment that is out of service, the maintenance administrator will manually request to fix it.

9. Events

An event's location, start date, duration, and name must be saved in the system, the supervisor's ID must be stored.

10. Health records

The health records for every member must be measured and saved. Also, the date of when the measurements were taken must be stored.

11. Contracts

In any contract, the details must be stated, start and end date, the payment method (cash or credit card), and any discounts or taxes that were applied should be recorded.

- Each employee must belong to a department, and each department must have at least one employee belonging to it. Number of employees in each department must be counted.
- Each employee must work in at most one branch, and each branch must have at least one employee. The number of current working employees in a branch must be counted.
- A branch must have several registered members, each member must go to one branch. The number of members applied in the branch should not exceed the branch's capacity.
- A branch must be managed by only one employee.
- A department must be managed by only one employee.
- A class must be instructed by a single instructor, and an instructor may instruct several classes.
- A locker can be owned by a single member. And a member can own only one locker.
- Each branch includes several lockers. Each locker must be found in a specific branch.
- Each branch must have several sports equipment, and an equipment must be located at a specific branch.
- An event must be supervised by at least one supervisor, and a supervisor may supervise several events.
- Each member must have at least one or more health records, each record with different record dates. If a month has passed since the last measurements were taken, the health records should be measured again.
- Each member must be assigned to one membership plan that is specified by the contract. The total cost for the membership plan including the applied taxes and discounts that the member has paid for will be stored.

1.4 Intended Output of the system

Queries:

- Display information of an employee, Member, and Membership plan by using its ID.
- Display information of a locker, branch, department, class, and equipment by using its number.
- To display a member health records, use the member's ID.
- Check the state of availability of any locker by using its number.
- Check the state of a specific machine (Out of service / In service) by using its number.
- Display any event information by using its name.
- If a branch cannot take any more members, the responsible employee can look for other available branches based on the request of the client.
- Display sports equipment's state of a specific branch.
- Display the classes schedule either by days or by specific hours or both.
- Display the classes held by a specific instructor using the instructor ID.

Transactions:

- An employee can update their address, phone number, and bank account.
- Modifying salary, department, and branch of an employee by the DBA.
- A member can update their contact information such as phone number, email, and social state.
- If a contract has expired, the contract data and the member information will be removed.
- Modifying a branch's number of working employees and members, the manager and working hours.
- Updating a department number of employees and replacing its manager.
- Modify any class's days, hours, room No, and instructor.
- Insert a new class to the schedule or remove one.
- Modify a locker's owner, password, and state.
- Adding a new plan to the system or deleting a stored plan.
- Modifying an event's start date, location, and its duration in case of need.
- Insert a new health record measurement of a member.

Invoices:

When a contract deal is done, the member will receive an invoice that contains the following information:

- Contract ID
- Member ID
- Plan's name
- Branch No
- Start date (Day, Month, Year)
- End date (Day, Month, Year)
- Date of payment (Day, Month, Year)
- Payment method (Cash/Credit card)
- Membership plan price
- Applied discounts
- Applied taxes
- Total cost

Calculations:

Using contracts information, we can calculate the monthly, and yearly profits of a certain branch. Based on that, we can decide whether a branch needs an adjustment in the number of employees. By using the date of payment of all contracts, we can determine the month with the highest enrolment rate and use that to offer exclusive deals and discounts to attract more customers to register in the GYM during these seasonal months. By observing the number of registered members in each branch, we can check if a branch has made the estimated profits. Based on that, a decision whether a branch should be shut down or not will be made.

2.2 Design of Business Rules

Business Rule	Design Decisions	Justification (if any)
A member must be at least 16 years old to apply to the GYM.	Derived attribute called **Age** that is computed from the subtraction of date of birth attribute and the current date.	If the computed age value was under 16 then this member instance validates the age constraint which we will show in upcoming phases (Implementation phase) how the database will deal with it.
Overall working hours of a branch should be at least 12 hours.	This done by having a composite attribute called **Working_Hours** which is composed of **Opening_Hours** and **Closing_Hours** attributes.	To make sure that the overall working hours is at least 12 in total, we can subtract the closing hour from the opening hour and check if the result was equal to or greater than 12.
To prevent overlapping, no two classes can occur at the same time, at the same room.	This is accomplished by making the classes entity have two key attributes, first one is the **ClassRefNumber**, and the other one is the **Place** attribute which is a composite attribute made up of: room number, hour, and day simple attributes.	From the perspective of the relation schema, which prevents a relation from having more than one primary key, we chose the place (which is made up of day, hour, and room number) as the primary key, because the unique combination of this composite key will prevent overlapping, and the class reference number will be the unique attribute.
The device's state and location must be recorded, in case of an equipment that is out of service, the maintenance administrator will manually request to fix it.	The **State** of a device is an attribute that can have either one of these two values: in service or out of service.	If the maintenance staff wishes to check which devices in a specific branch needs to be fixed, they can simply check the recorded states of the devices in a specific branch.

Each branch must have several sports equipment, and an equipment must be located at a specific branch.	This is implemented by creating a one-to-many relationship between the branches and sports equipment entities that is called **Located_In**.	This relationship shows total participation from branches entity because a branch cannot be classified as a gym branch without having sports equipment. And it shows total participation from the sports equipment side because an equipment needs to be located in a branch in order to be used by members.
Each employee must Belong to a department, and each department must have at least one employee belonging to it. Number of employees in each department must be counted.	This is implemented by creating a many-to-one relationship between the employees and departments entities that is called **Belong_To**. **Number of employees** will be a derived attribute in the departments entity.	The derived attribute number of employees is computed from the relationship **Belong_To** which counts the total number of employees in each specific department. Also, this relationship shows total participation from the departments because a department cannot exist without having employees. At the same time, it shows total participation from the employees because each employee must belong to one department.
Each employee must work in at most one branch, and each branch must have at least one employee. The number of current working employees in a branch must be counted.	This is implemented by creating a many-to-one relationship between the employees and branches entities that is called **Works_In**. **Number of employees** will be a derived attribute in the branches entity.	The derived attribute number of employees is computed from the relationship **Works_In** which counts the total number of employees currently working in each specific branch. Also, this relationship shows total participation from both participating entities. From the branches side, a branch does not exist without having employees. At the same time, an employee must be working in a single branch.

A branch must have several registered members, each member must go to one branch. The number of members applied in the branch should not exceed the branch's capacity.	This is implemented by creating a one-to-many relationship between the branches and members entities that is called **Has**. **Number of members** will be a derived attribute in the branches entity.	The derived attribute number of members is computed from the relationship **Has** which counts the total number of members in each specific branch, this computed value should not exceed the specific capacity of the branch. also, this relationship shows total participation from both participating entities. A branch cannot exist without having registered members, and each member must be registered in a single branch.
A branch must be managed by only one employee.	This is implemented by creating a one-to-one relationship between the employees and branches entities that is called **Branch_Mgr**.	This relationship shows total participation from the branches entity, because all branches must have a manager, and shows partial participation from the employees entity, because not all employees have to manage a branch.
A department must be managed by only one employee.	This is implemented by creating a one-to-one relationship between the employees and departments entities that is called **Dep_Mgr**.	This relationship shows total participation from the departments entity, because all departments must have a manager, and shows partial participation from the employees entity, because not all employees have to manage a department.
A class must be instructed by a single instructor, and an instructor may instruct several classes.	This is implemented by creating a one-to-many relationship between the employees and classes entities that is called **Instructed_by**.	This relationship shows total participation from the classes entity, since a class must be instructed by an employee, and partial participation from the employees entity, since not all employees are instructors.
A locker can be owned by a single member. And a member can own only one locker.	This is implemented by creating a one-to-one relationship between the lockers and members entities that is called **Owned_by**.	This relationship shows partial participation from both participating entities, because not all lockers are occupied by members, and not all members own lockers.

Each branch includes several lockers. Each locker must be found in a specific branch.	This is implemented by creating a one-to-many relationship between the branches and lockers entities that is called **Include**.	This relationship shows total participation from both participating entities. Because each branch needs to have lockers for its members and each locker needs to be located in a specific branch.
An event must be supervised by at least one supervisor, and a supervisor may supervise several events.	This is implemented by creating a many-to-many relationship between the events and employees entities that is called **Supervised_by**.	This relationship shows total participation from the events entity, because each event must be supervised by one or more supervisors to manage and organize the event, and it shows partial participation from the employees entity, because not all employees are qualified to supervise an event.
Each member must have at least one or more health records, each record with different record dates.	This is implemented by creating a many-to-one relationship between the members and health records entities that is called **Record_Of**. This relationship is considered as an identifying relationship for the weak entity that is health records, and the owner entity is the members entity. The **date of record** attribute for the health records entity is its partial key, and the key that distinct each health record instance is a unique combination of the **member id** and the **date of record**.	This relationship is one-to-many because several health records will belong to one member, only difference between each record is the date of when it was taken, and each member may have many health records. This relationship must show total participation from the weak entity (health records) side because it is existence dependent and shows total participation from the members entity, because all members of the gym will have their measurements taken each month.
If a month has passed since the last measurements were taken, the health records should be measured again.	The **Date of record** for the health records entity is an attribute that takes the role of the date of when the records of a member were measured.	The medical care administrator will check the last month's recorded health measurements of some members to ensure that a month has passed since the records were last taken, and to also check if they need to retake them again for these members.

Each member must be assigned to one membership plan that is specified by the contract. The total cost for the membership plan including the applied taxes and discounts that the member has paid for will be stored.	This is implemented by creating a ternary relationship that is called **Assigned_To,** which is one-to-one among the members, membership plans and contracts entities. The **total cost** is an attribute of the ternary relationship.	This relationship shows total participation from the contracts side because a contract instance will not exist without being assigned to a specific member, and it shows total participation from the members side because when a member is assigned to a membership plan in the gym, they must have a contract that shows all the registration details. The relationship also shows partial participation from the membership plans entity because a membership plan can exist in the system without having to be assigned to any members.

3 ER-to-logical Schema Mapping

3.1 Mapping of Regular Entity Types

To map regular strong entity types from ER to relation schema, we must create a relation that includes all the simple attributes that form the entity, unlike the ER diagram, relational schema disallows an entity to have more than one key attribute as the primary key for the relation , that is why when mapping an ER entity to relation schema we must choose one of its key attributes as the primary key for the relation schema. Also, if an entity had an attribute that is composed of more than one simple attribute, we map the simple attributes that form this composite attribute to the relation schema.

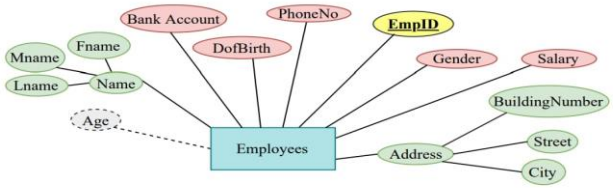
- Mapping of Employees entity

  We mapped all the simple attributes in the employees entity, and we also mapped the simple attributes that form the composite attribute (Name and Address) in the entity. The primary key of the employees relational schema is the key attribute of the employees entity which is EmpID.

  The age attribute is a derived attribute that will not be mapped when mapping the entity to relational schema, the derived attributes will be handled at the implementational phase.

Employees

EmpID	Fname	Mname	Lname	DofBirth	PhoneNo	Gender	Salary	Bank Account	City	Street	BuildingNumber



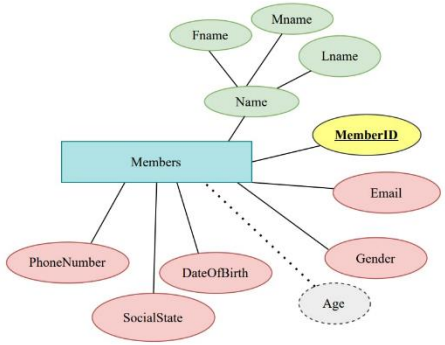
- Mapping of Members entity

We mapped all the simple attributes in the members entity, and we also mapped the simple attributes that form the composite attribute (Name) in the entity. The primary key of the members relational schema is the key attribute of the members entity which is MemberID.

The age attribute is a derived attribute that will not be mapped when mapping the entity to relational schema, the derived attributes will be handled at the implementational phase.

Members

MemberID	Fname	Mname	Lname	Email	Gender	DateOfBirth	SocialState	PhoneNumber



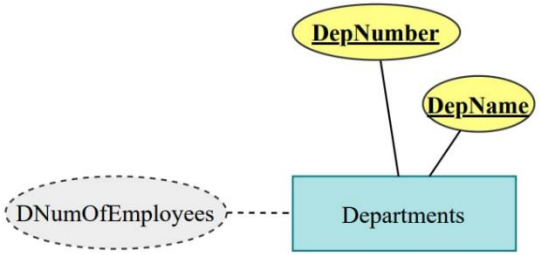
- Mapping of departments entity

Since the departments entity contain two key attributes which are the DepNumber and DepName and contains no simple attributes, we chose DepNumber as the primary key of the departments relational schema and the other key attribute (DepName) will be a candidate key (unique).

The DNumOfEmployees attribute is a derived attribute that will not be mapped when mapping the entity to relational schema, the derived attributes will be handled at the implementational phase.

Departements

DepNumber	DepName

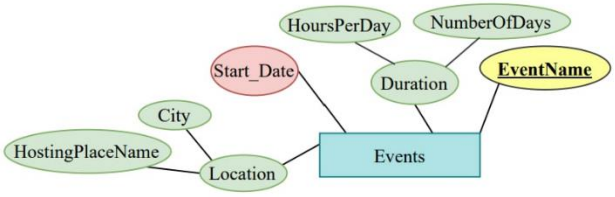


- Mapping of events entity

We mapped the simple attribute in the events entity, and we also mapped the simple attributes that form the composite attribute (Location and Duration) in the entity. The primary key of the events relational schema is the key attribute of the events entity which is EventName.

Events

EventName	Start_Date	NumberOfDays	HoursPerDay	City	HostingPlaceName



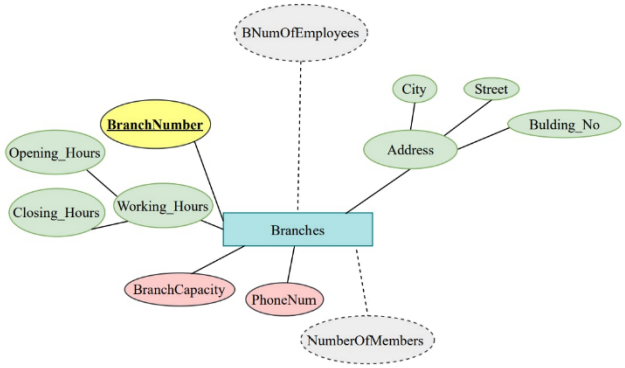
- Mapping of branches entity

We mapped all the simple attributes in the branches entity, and we also mapped the simple attributes that form the composite attribute (Working_Hours and Address) in the entity. The primary key of the branches relational schema is the key attribute of the branches entity which is BranchNumber.

The BNumOfEmployees attribute and NumberOfMembers are derived attributes that will not be mapped when mapping the entity to relational schema, the derived attributes will be handled at the implementational phase.

Branches

BranchNumber	City	Street	Building_No	PhoneNum	BranchCapacity	Opening_Hours	Closing_Hours

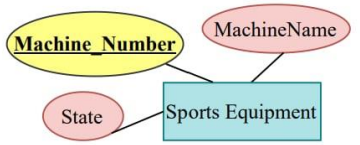


- Mapping of sports equipment entity

We mapped all the simple attributes in the sports equipment entity. The primary key of the sports equipment relational schema is the key attribute of the sports equipment entity which is Machine_Number.

Sports Equipment

Machine_Number	MachineName	State

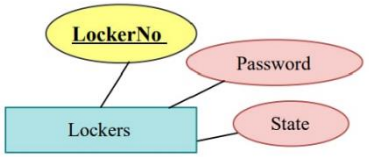


- Mapping of lockers entity

We mapped all the simple attributes in the lockers entity. The primary key of the lockers relational schema is the key attribute of the lockers entity which is LockerNo.

Lockers

LockerNo	Password	State

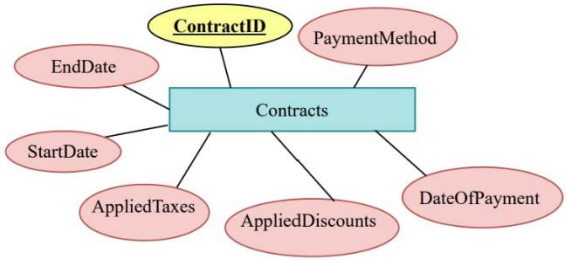


- Mapping of contracts entity

We mapped all the simple attributes in the contracts entity.The primary key of the contracts relational schema is the key attribute of the contracts entity which is ContractID.

Contracts

ContractID	StartDate	EndDate	PaymentMethod	AppliedDiscounts	AppliedTaxes	DateOfPayment



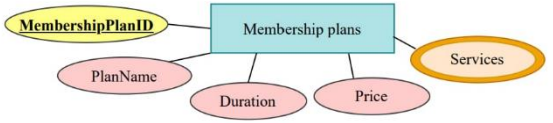
- Mapping of membership plans entity

We mapped all the simple attributes in the membership plans entity. The primary key of the membership plans relational schema is the key attribute of the membership plans entity which is MembershipPlanID.

The services attribute is a multivalued attribute that will not be mapped in the same relational schema when mapping the regular entity type, but we will show how we will map it at section 3.6.

Membership Plans

MembershipPlanID	PlanName	Duration	Price

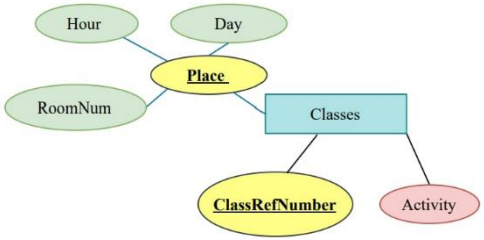


- Mapping of classes entity

We mapped the simple attribute in the classes entity, and we also mapped the simple attributes that form the composite attribute (Place) in the entity. Since the classes entity contain two key attributes which are the Place and ClassRefNumber, we chose Place as the primary key of the classes relational schema and the other key attribute (ClassRefNumber) will be a candidate key (unique). The primary key Place of classes relational schema is composite, so the set of the simple attributes that form it (Hour,Day,RoomNum) will together form the composite primary key of the relational schema.

Classes

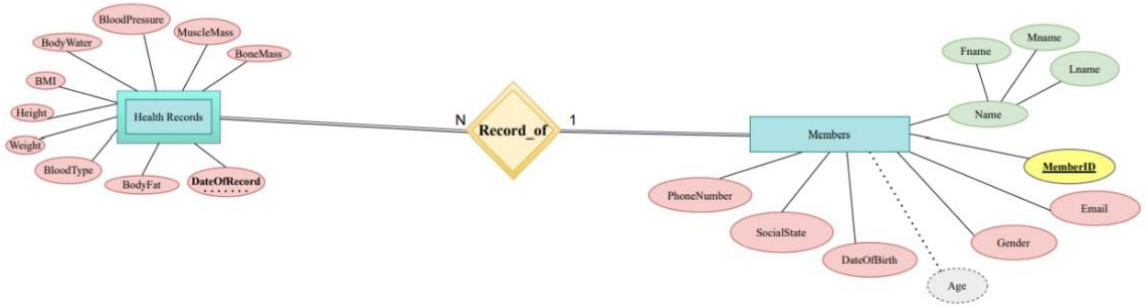
Day	**Hour**	**RoomNum**	ClassRefNumber	Activity



3.2 Mapping of Weak Entity Types

- Mapping of health records weak entity

  The weak entity health records is owned by the members entity. When mapping the health records entity, we will create a relation schema which will contain all of the simple attributes (as well as the simple attributes of any composite attribute if the weak entity had one) of the entity. To show the relationship between the owning entity (members) as well as the weak entity (health records), we will include in the relation schema of health records a foreign key which is MemId that references the primary key of the owner entity (members). The combination of the foreign key (MemId) and the partial key (DateOfRecord) will together form the primary key of the health records relation schema.



Members

MemberID	Fname	Mname	Lname	Email	Gender	DateOfBirth	SocialState	PhoneNumber

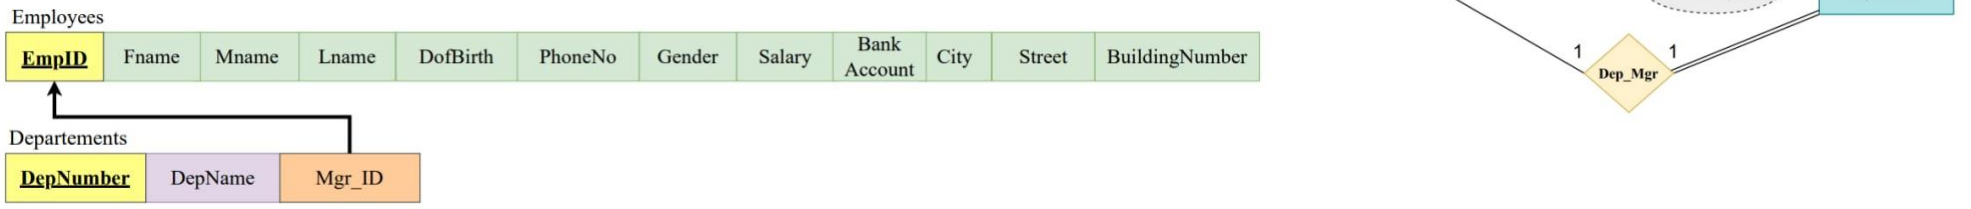
Health Records

MemId	DateOfRecord	BodyFat	BloodType	Weight	Height	BMI	BodyWater	BloodPressure	MuscleMass	BodyMass

3.3 Mapping of Binary 1-1 Relationship Types

- Mapping of Dep_Mgr relationship

  To map the binary 1:1 Dep_Mgr relation between the Departments and Employees entities, we will consider the approach of adding a foreign key to one of the participating entities in the relation, it is better to include a foreign key in the entity that shows total participation to reduce Null values in the tuples of the relation schema. That is why we chose to add a foreign key (Mgr_ID) in the departments relation that references the primary key (EmpId) of the employees relation.



- Mapping of Branch_Mgr relationship

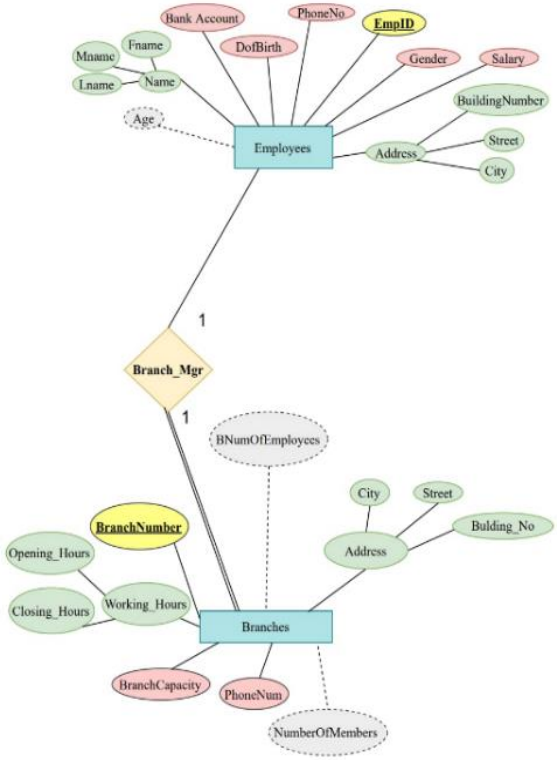
To map the binary 1:1 Branch_Mgr relation between the Branchess and Employees entities, we will consider the approach of adding a foreign key to one of the participating entities in the relation, it is better to include a foreign key in the entity that shows total participation to reduce Null values in the tuples of the relation schema. That is why we chose to add a foreign key (Manager_ID) in the branches relation that references the primary key (EmpId) of the employees relation.

Employees

EmpID	Fname	Mname	Lname	DofBirth	PhoneNo	Gender	Salary	Bank Account	City	Street	BuildingNumber

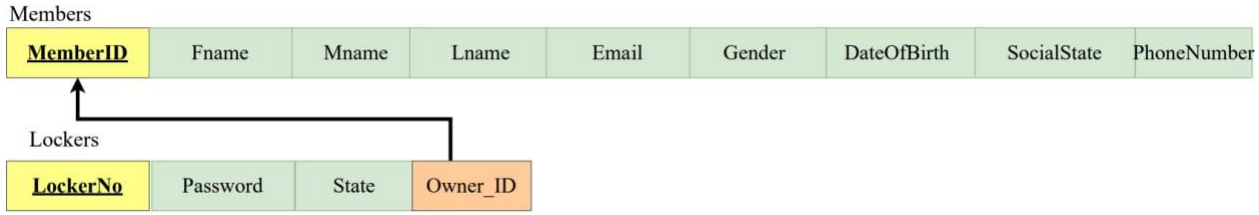
Branches

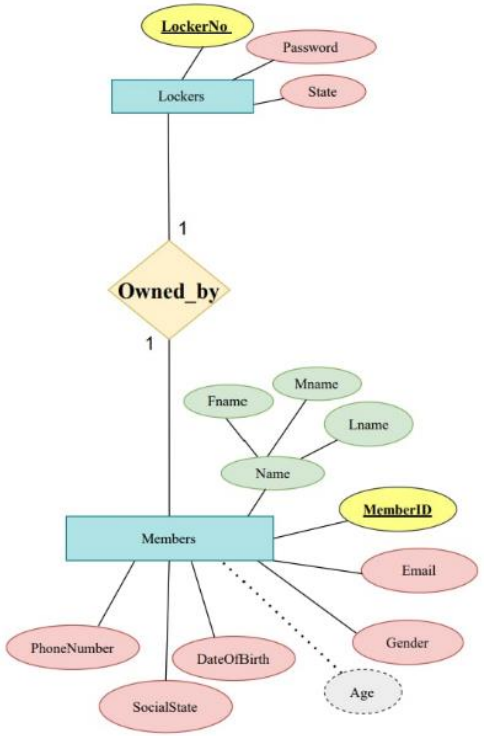
BranchNumber	City	Street	Building_No	PhoneNum	BranchCapacity	Opening_Hours	Closing_Hours	Manager_ID



- Mapping of Owned_By relationship

To map the binary 1:1 Owned_by relation between the Lockers and Members entities, we will consider the approach of adding a foreign key to one of the participating entities in the relation , it is better to include a foreign key in the entity that shows total participation to reduce Null values in the tuples of the relation schema, if both of the participating entities show partial participation in the relationship , it will make no difference to choose which relation schema to add the foreign key in. We chose to add a foreign key (Owner_ID) in the Lockers relation that references the primary key (MemberID) of the members relation.





3.4 Mapping of Binary 1-N Relationship Types

To map a 1:N relationship, we will include a foreign key that references the primary key of the relation that represent the participating entity at the 1-side of the relationship in the relation that represent the participating entity at the N-side of the relationship.

- Mapping of Has relationship

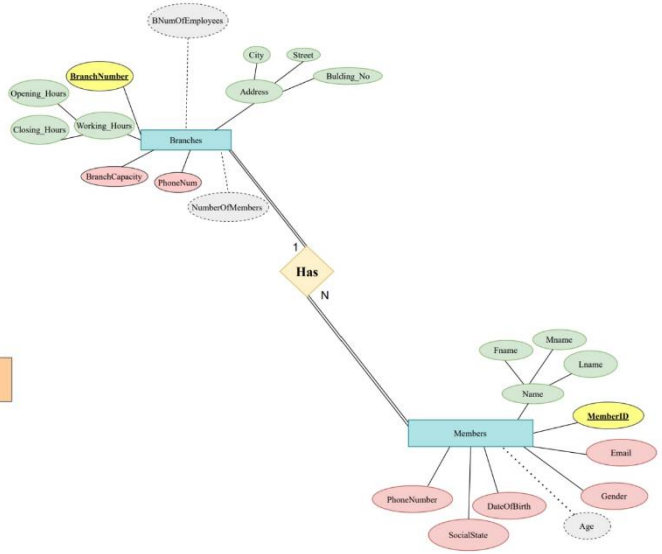
To map the Has relationship between the Branches and members entities, we will include a foreign key in the relation that represents the entity at the N-side of the relationship which is members. The foreign key BranchNo in the members relation will reference the primary key of the branches relation that represents the branches entity at the 1-side of the relationship.

Branches

BranchNumber	City	Street	Building_No	PhoneNum	BranchCapacity	Opening_Hours	Closing_Hours	Manager_ID

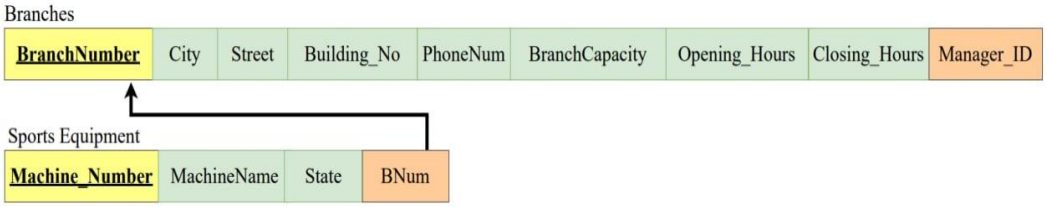
Members

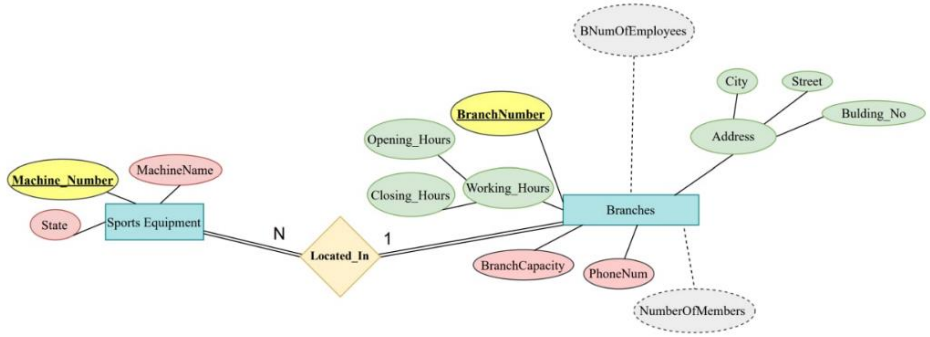
MemberID	Fname	Mname	Lname	Email	Gender	DateOfBirth	SocialState	PhoneNumber	BranchNo



- Mapping of Located_In relationship

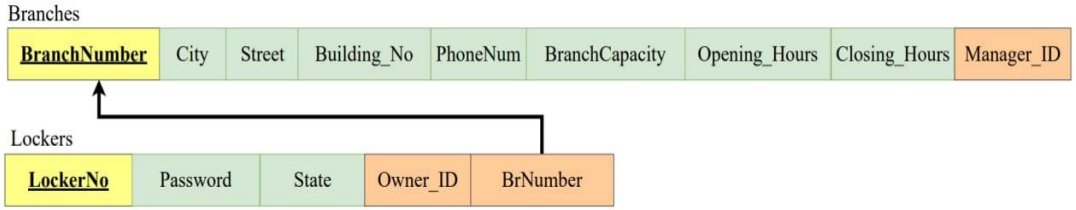
To map the Located_In relationship between the Branches and sports equipment entities, we will include a foreign key in the relation that represents the entity at the N-side of the relationship which is sports equipment. The foreign key BNum in the sports equipment relation will reference the primary key of the Branches relation that represents the branches entity at the 1-side of the relationship.

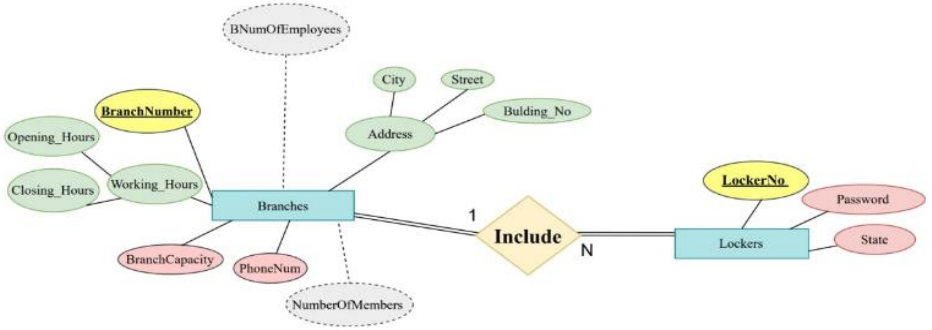




- Mapping of Include relationship

To map the Include relationship between the Branches and Lockers entities, we will include a foreign key in the relation that represents the entity at the N-side of the relationship which is Lockers. The foreign key BrNumber in the Lockers relation will reference the primary key of the branches relation that represents the branches entity at the 1-side of the relationship.





- Mapping of Instructed_By relationship

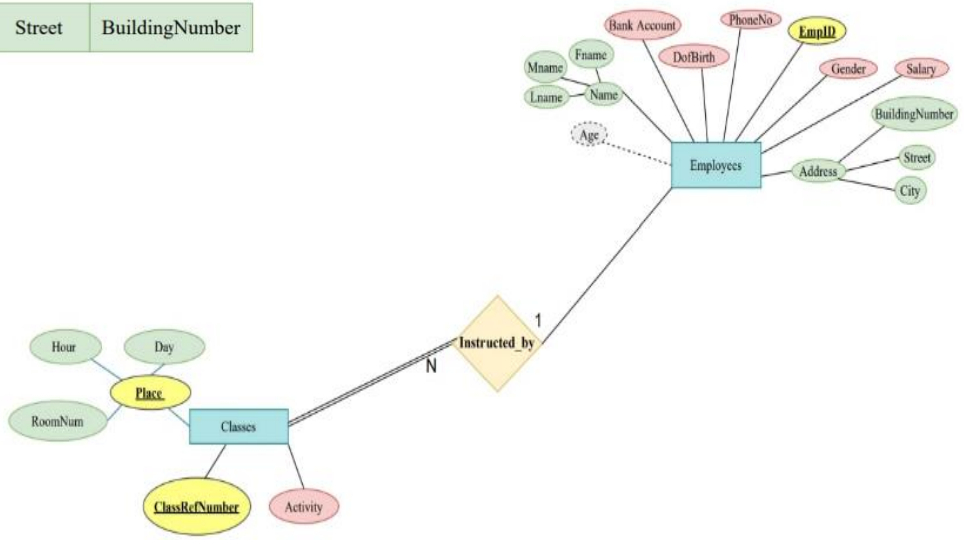
  To map the Instructed_By relationship between the Classes and Employees entities, we will include a foreign key in the relation that represents the entity at the N-side of the relationship which is Classes. The foreign key InstructerID in the Classes relation will reference the primary key of the employees relation that represents the employees entity at the 1-side of the relationship.

Employees

EmpID	Fname	Mname	Lname	DofBirth	PhoneNo	Gender	Salary	Bank Account	City	Street	BuildingNumber

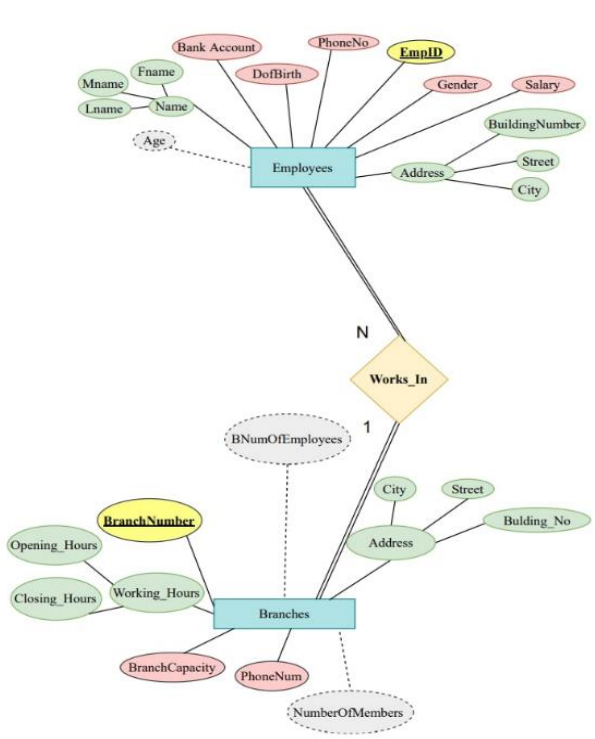
Classes

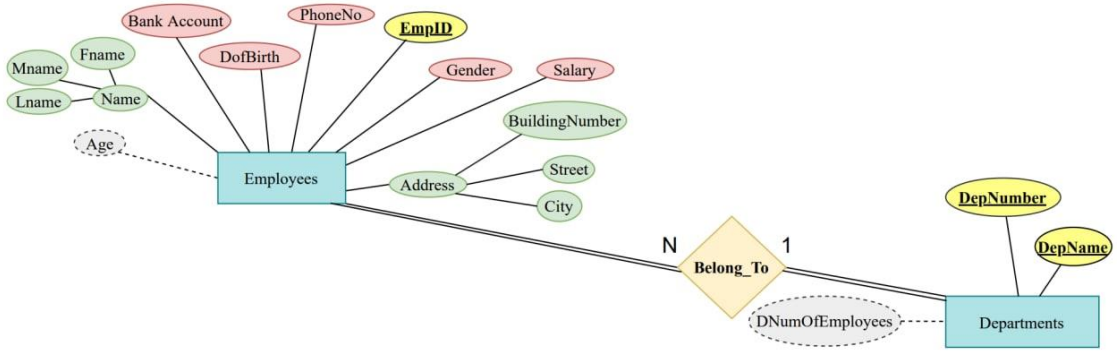
Day	**Hour**	**RoomNum**	ClassRefNumber	Activity	InstructerID

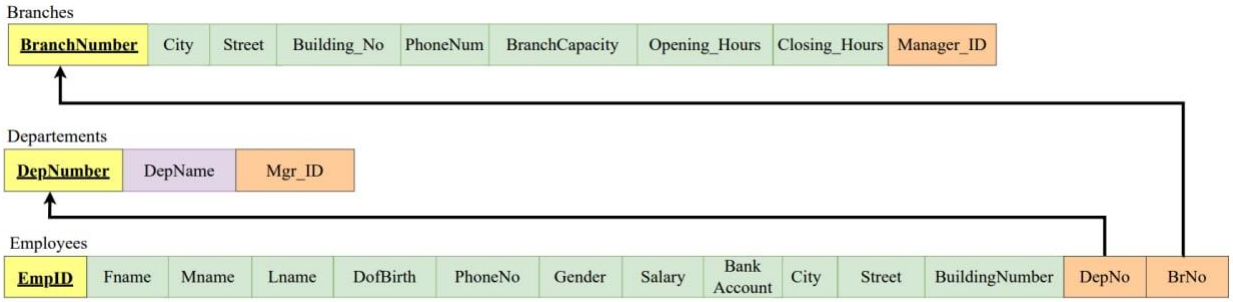


- Mapping Belong_To and Works_In relationships

When mapping the Belong_To relation between employees and departments as well as the Works_In relation between the employees and branches relation, we included two foreign keys in the employees relation because the entity employees is at the N-side of the both of the relationships. The first one is DepNo that references the primary key of the departments relation, and the second foreign key is BrNo that references the primary key of the branches relation, because both of these participating entities were at the 1-side of both of the relationships.



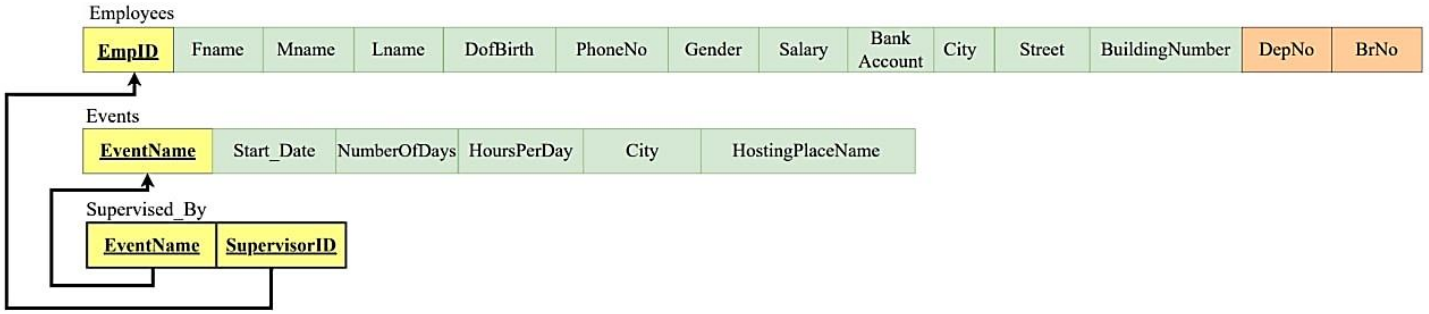


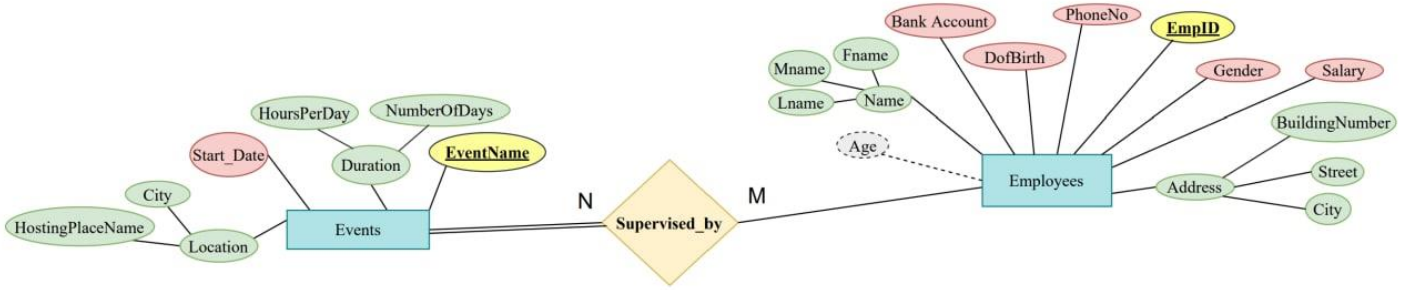


3.5 Mapping of Binary M-N Relationship Types

- Mapping of Supervised_By relationship

  To map the M:N relationship that is Supervised_By between the Events and Employees entities, we will create a new relation for the relationship. This relation will contain two foreign keys (EventName and SupervisorID) that references both participating entities (employees and events) primary keys. Together, these two foreign keys will form the primary key of this relation.

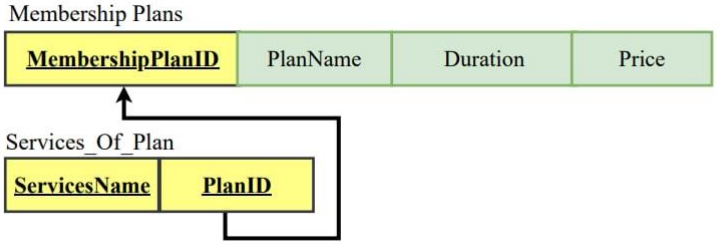


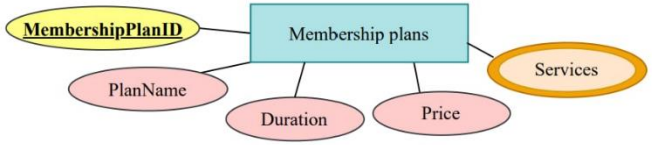


3.6 Mapping of Multivalued Attributes

- Mapping Services multivalued attribute of the membership plans entity

  To map the services multivalued attribute of the membership plans entity, we will create a sperate relation for this attribute. This relation will be called Services_Of_Plan and it will include a foreign key (PlanID) that references the primary key of the relation that represents the entity that has this multivalued attribute (membership plans), and it will also include an attribute (ServicesName) that represents each value of this multivalued attribute. These two values (PlanID and SevicesName) will be the primary key of the new relation.

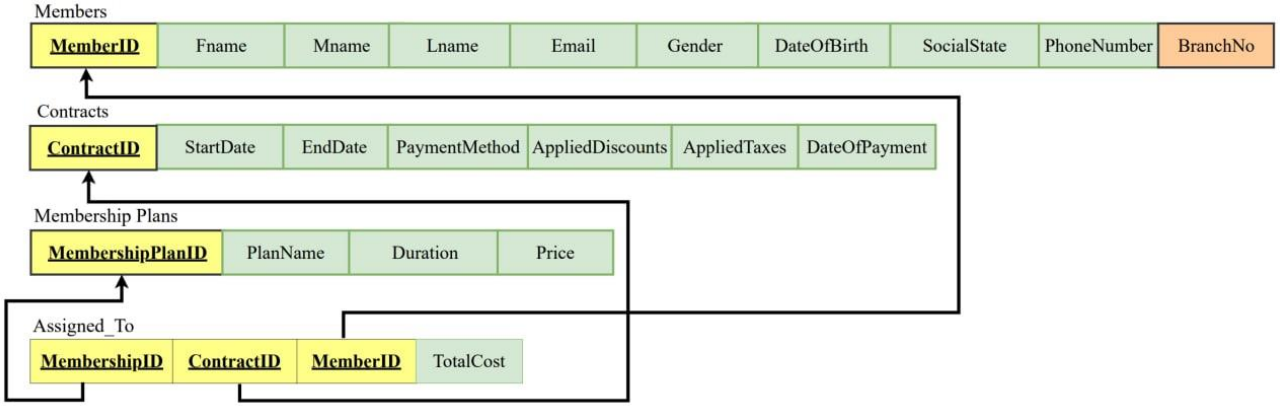


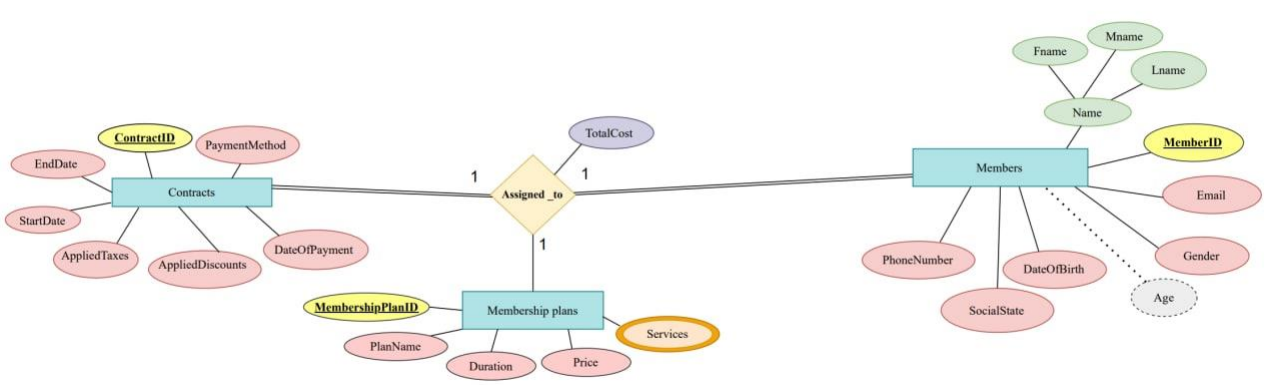


3.7 Mapping of N-ary Relationship Types

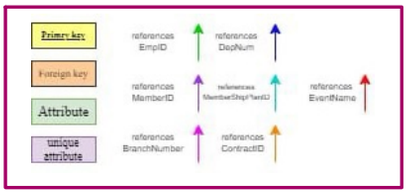
- Mapping of Assigned_To ternary relationship

To map the ternary relationship Assigned_To between contracts, members, and membership plans entities, we will create a new relation called Assigned_To to show this relationship. This relation will contain foreign keys (MembershipID, ContractID, and MemberID) that will reference all of the primary keys of the participating entities that are represented by these referenced relations. Also, the relation must include any attribute of the relationship itself which is TotalCost in this relationship. The primary of this relation will be composed of all the foreign keys in the relation.





3.9 Schema Diagram



Employees

4 Normalization

4.1 First Normal Form

For a relational schema to be in first normal form, it should not contain composite attributes as well as multivalued attributes and nested relations.

Composite attribute is an attribute that is composed of more than one simple attribute, like the Address, Name, Place attributes in members, employees, and classes entities that are in the ER diagram in section 2.1.

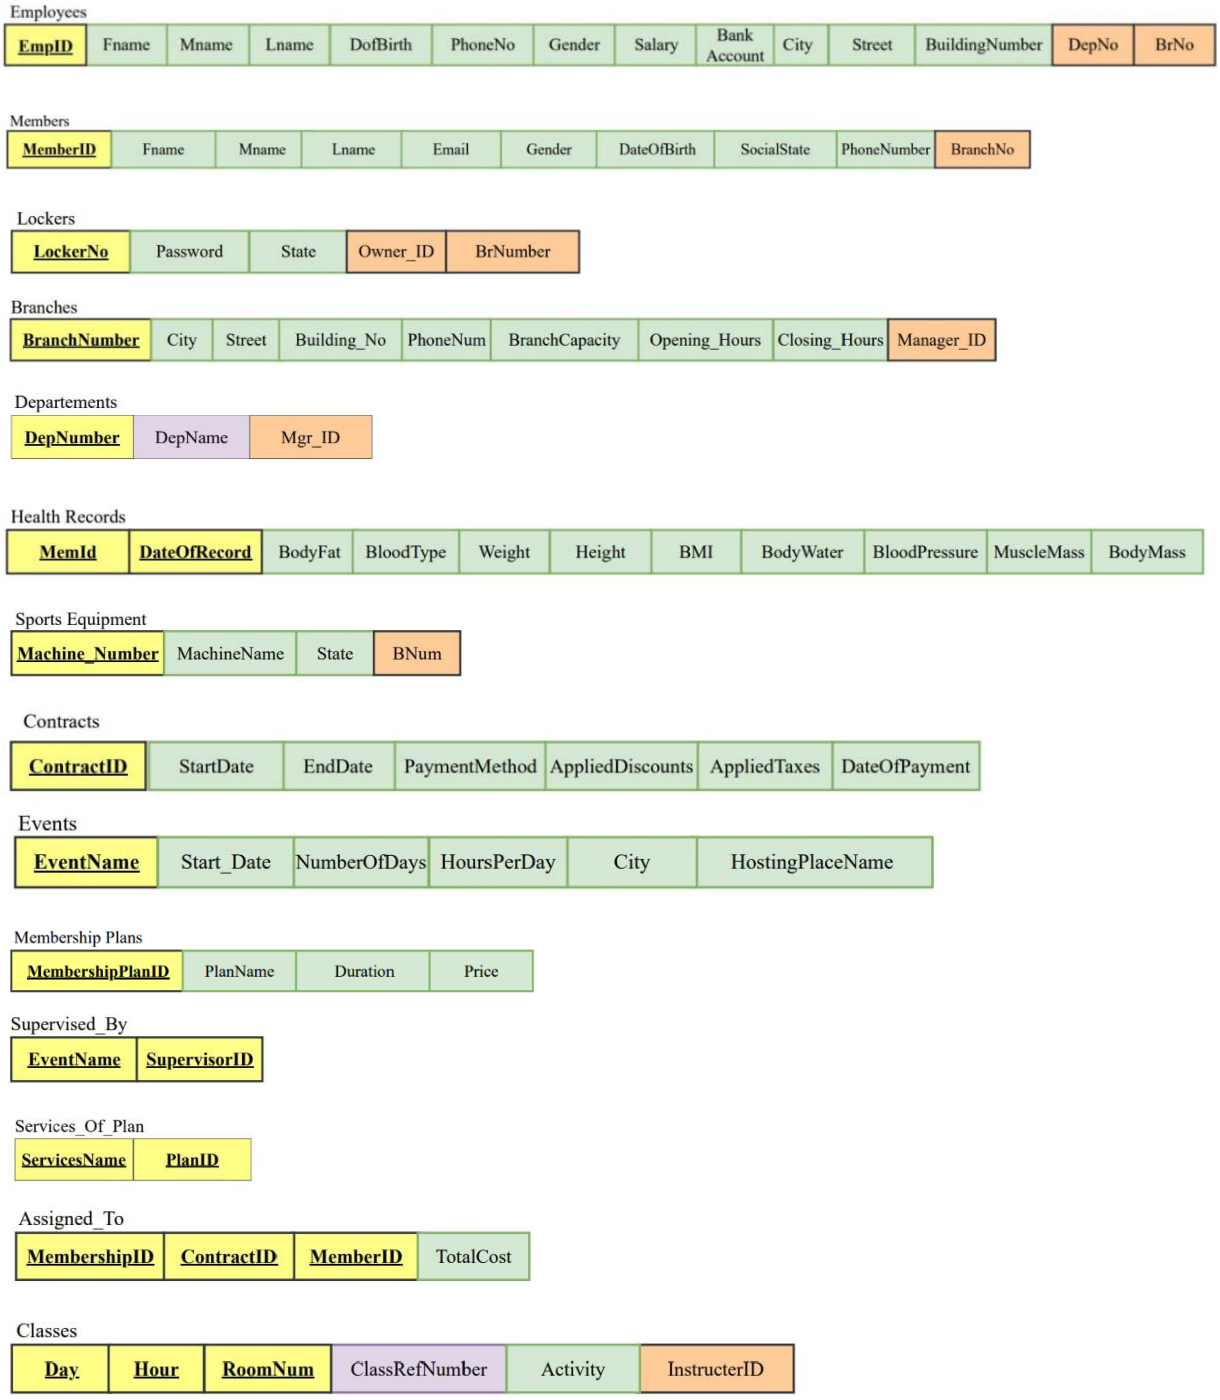
To map composite attributes to the first normal form of relational schema, we mapped the simple attributes that made the composite attribute into the relational schema. We have already done this when mapping the regular entities of our ER diagram into relational schemas shown in section 3.1.

Multivalued attribute is an attribute that can take several values for the same instance, in our ER diagram we had only one multivalued attribute in the membership plans entity which is services, shown in section 2.1.

In order to map multivalued attributes to the first normal form of relational schema, we mapped the multivalued attribute by separating it in a new relational schema along with the primary key of its regular entity that is represented in a relational schema. We have done this while mapping the services attribute of membership plans entity into a separate relation with the primary key of membership plans relation which is membership plan ID in section 3.6.

Nested relations are attributes that can represent relations within themselves. Our ER diagram does not include any nested relations.

The final relational schema diagram after normalizing it to the first normal form is as follows:



4.2 Second Normal Form

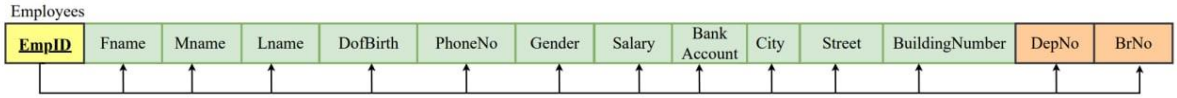
To normalize a relational schema into the second normal form, all non-prime attributes should be fully functionally dependent on the prime attribute(s) of the relation.

A prime attribute is an attribute that make up the relation's primary key, if a relation had a composite primary key, then the set of attributes that make up the primary key are called prime attributes.

From the above definition of prime attributes, we can conclude that any attribute in the relation that is not a part of the primary key will be called a non-prime attribute.

- Employees:

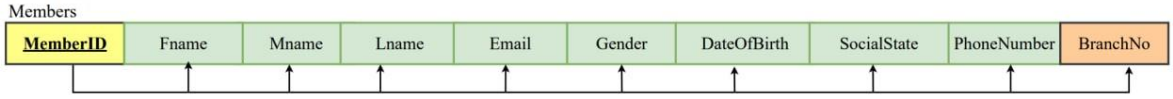
  The employees relation has only one prime attribute that is EmpID. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute EmpID. Therefore, the employees relation is in second normal form.



{EmpID} -> Fname, Mname, Lname, DofBrith, PhoneNo, Gender, Salary, BankAccount, City, Street, BuildingNumber,DepNo,BrNo.

- Members:

  The Members relation has only one prime attribute that is MemberID. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute MemberID. Therefore, the Members relation is in second normal form.



{MemberID}-> Fname,Mname,Lname,Email,Gender,DateOfBirth,SocialState,

PhoneNumber,Street, BranchNO.

- Lockers:

  The Lockers relation has only one prime attribute that is LockerNo. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute LockerNo. Therefore, the Lockers relation is in second normal form.

  {LockerNo}-> Passwor,State,OwnerID,BrNumber.

- Branches:

  The Branches relation has only one prime attribute that is BranchNumber. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute BranchNumber. Therefore, the branches relation is in second normal form.

  {BranchNumber}-> City, Street,Building_No, BranchCapacity, Opening_Hours, Closing_Hours, Manger_ID.

- Departments:

  The Departments relation has only one prime attribute that is DepNumber. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute DepNumber. Therefore, the Departments relation is in second normal form.

  {DepNumber}-> DepName, Mgr_ID.

- Health Records:

  The Health Records relation has two prime attributes that are MemID and DateOfRecord. All the non-prime attributes in the relation are fully functionally dependent on both of the prime attributes MemID and DateOfRecord. Therefore, the Health Records relation is in second normal form.

  {MemID,DateOfRecord}-> BodyFat, BloodType, Weight, Height, BMI, BodyWater, BloodPressure, MuscleMass, BodyMass.

  The removal of any one of the two prime attributes means that the functional dependency will not hold anymore. Proving that all the non-prime attributes are fully functionally dependent on both prime attributes.

  Example:

  Suppose a member instance had a member ID that is 1234, and its health records were taken at 4th of March 2022, the same member had its health records remeasured at 4th of April 2022. That is why each non-prime attribute will be fully functional dependent on this combination of prime attributes. To show that each instance of the health records for this member is different, we chose to make both date of record as well as the member ID prime attributes (composite key) to enforce the functional dependency on the combination of both attributes.

  {1234,04/03/2022}-> body mass is deferent than {1234,04/04/2022} -> body mass. That is why each non-prime attribute will be fully functional dependent on this combination of prime attributes

- Sports Equipment:

  The Sports equipment relation has only one prime attribute that is Machine_Number. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute Machine_Number. Therefore, the Sports equipment relation is in second normal form.

  {Machine_Number}-> MachineName,State,BNum.

- Contracts:

  The contracts relation has only one prime attribute that is ContractID. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute ContractID. Therefore, the contracts relation is in second normal form.

  {ContractID}-> StartDate, EndDate,PaymentMethod, AppliedDiscounts, AppliedTaxes, DateOfPayment.

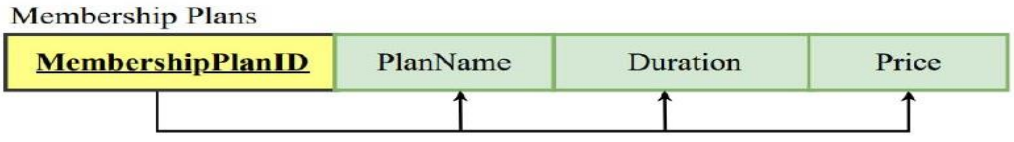
- Events:

  The Events relation has only one prime attribute that is EventName. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute EventName. Therefore, the Events relation is in second normal form.

  {EventName}-> Start_Date, NumberOfDays, HoursPerDay, City, HostingPlaceName.

- Membership plans:

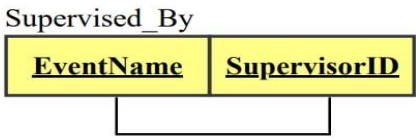
  The Membership Plans relation has only one prime attribute that is MembershipPlanID. All the non-prime attributes in the relation are fully functionally dependent on the prime attribute MembershipPlanID. Therefore, the Membership Plans relation is in second normal form.



{MembershipPlanID}-> PlanName, Duration,Price

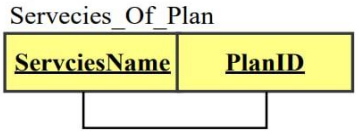
- Supervised_By:

  The Supervised_By relation has only two prime attributes that are EventName and SupervisorID and it contains no non-prime attributes. Therefore, the Supervied_By relation is in second normal form. If the Supervised_By relation had any non-prime attributes, then we will need to prove that the non-prime attributes are fully functional dependent on the prime attributes and if not, we must normalize them to the second normal form.



- Services_Of_Plan:

  The Services of plan relation has only two prime attributes that are ServicesName and PlanID and it contains no non-prime attributes. Therefore, the Services of plan relation is in second normal form. If the services of plan relation had any non-prime attributes, then we will need to prove that the non-prime attributes are fully functional dependent on the prime attributes and if not, we must normalize them to the second normal form.



- Assigned_To:

  The Assigned relation has three prime attributes that are MembershipID, ConractID, and MemberID, the only non-prime attribute in the relation is fully functionally dependent on all of the prime attributes MembershipID, ConractID, and MemberID. Therefore, the Assigned relation is in second normal form.

  The total cost of a contract for any member will be different depending on the membership plan that the member has been assigned to after applying to the gym, as well as the applied taxes and applied discounts to this contract. Showing that the total cost is fully functional dependent on all the three prime attributes.

  {MembershipID, ConractID, MemberID}-> TotalCost.

- Classes:

  The classes relation has three prime attributes that are Day,Hour and RoomNum. All the non-prime attributes in the relation are fully functionally dependent on the three prime attributes Day, Hour and RoomNum. Therefore, the classes relation is in second normal form.

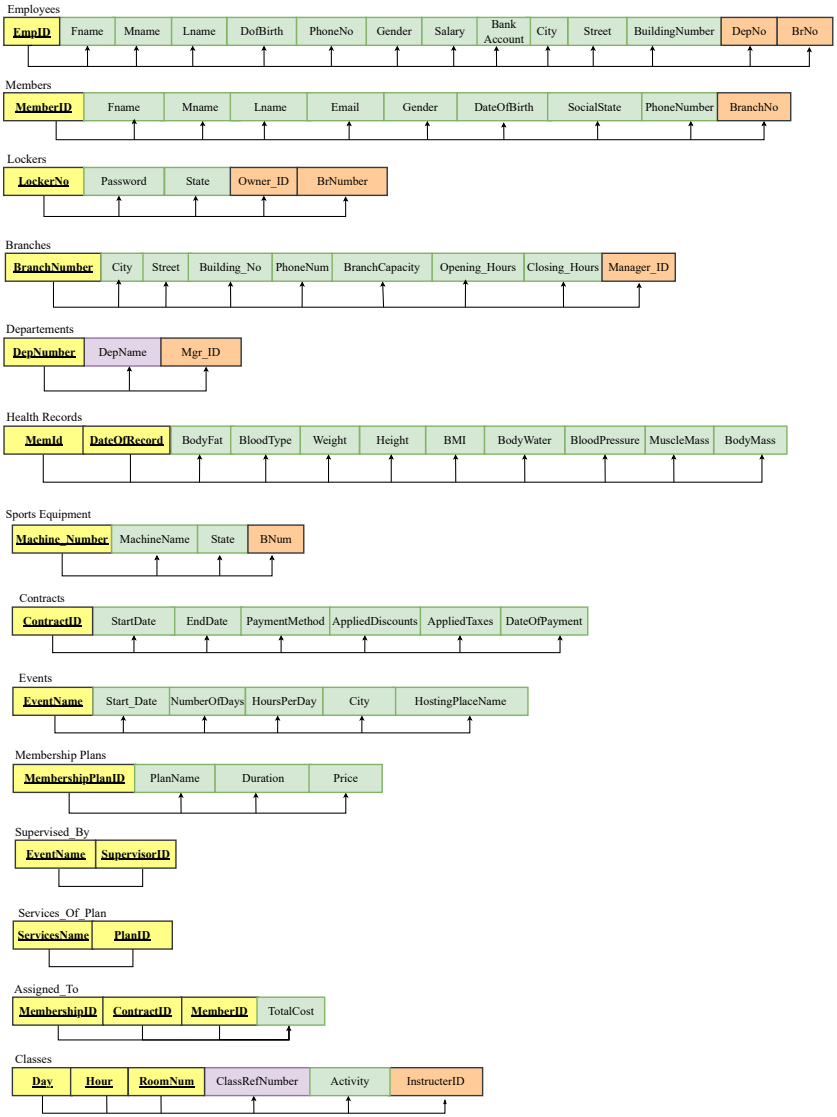
  To show that each instance of classes is different as well as to prevent overlapping, we chose to make the Day, Hour, RoomNum prime attributes for the classes relation.

  For example, the class that is held on Friday at 5 PM room number 6 has 1234 as its reference number (ClassRefNumber). This class is different than the class that is held on Friday at 6 PM room number 6 that has 2468 as its reference number (ClassRefNumber). This shows that the classes instances differ depending on the combination of these three attributes.

  {Day, Hour, RoomNum}-> ClassRefNumber, Activity, InstructerID.

  That is why each non-prime attribute will be fully functional dependent on this combination of prime attributes.

Final relation schema in 2NF:



Employees
EmpID

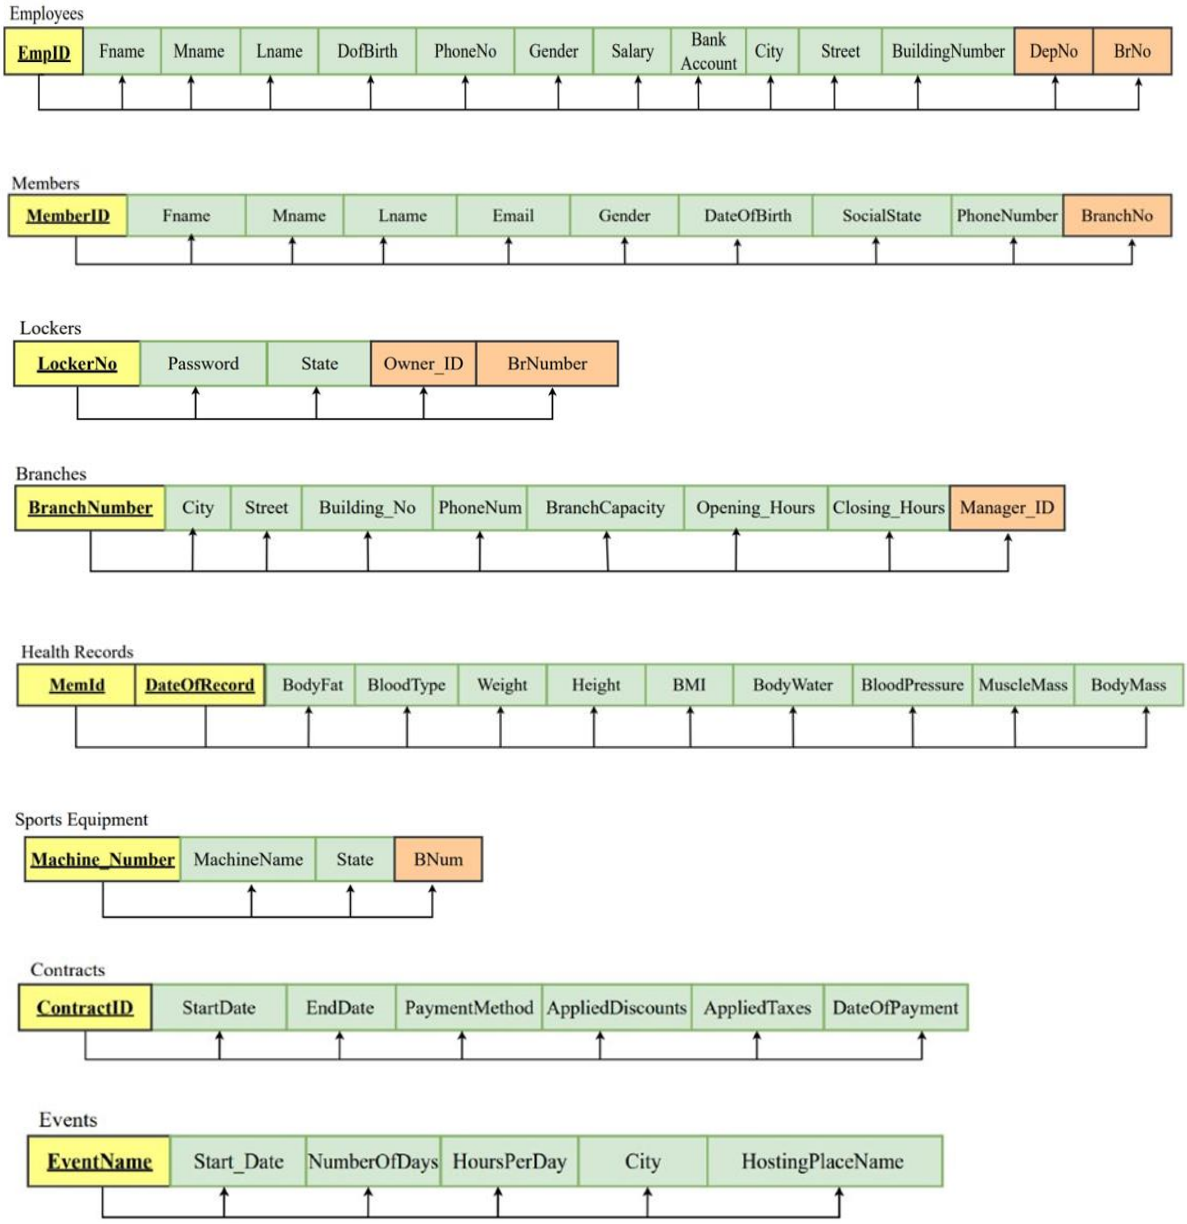
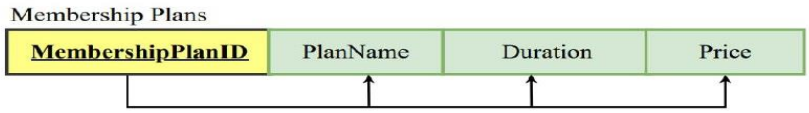
4.3 Third Normal Form

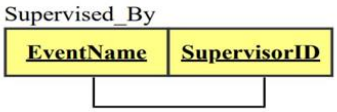
To normalize a relation in third normal form, we must remove all transitive dependencies on the primary key.

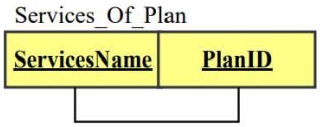
Transitive dependency is when a non-prime attribute is functionally dependent on another non-prime attribute. Third normal form allows transitive dependency only when the non-prime attribute the other non-prime attributes are functionally dependent on is a candidate key (unique).

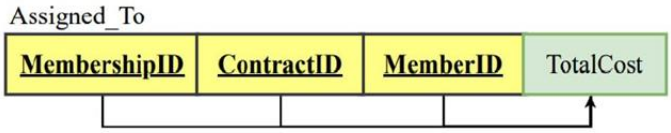
In section 4.2, we have normalized all relational schemas into the second normal form. Now we will list all of the relational schemas that are already in third normal form since they do not include any transitive dependency on the primary key.





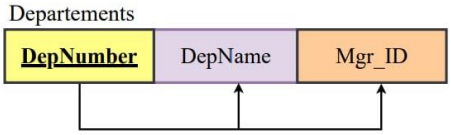






- Departments:

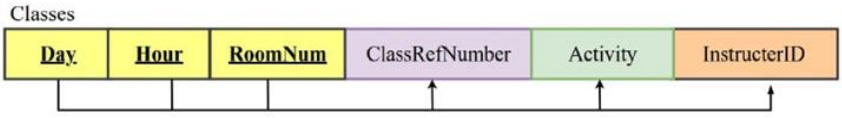
  In departments relation schema, there is a functional dependency on a non-prime attribute which is DepName to another non-prime attribute which is Mgr_ID. Even though it is considered to be a transitive depency which is disallowed in third normal form, it is however acceptable in this case because the non-prime attribute that the other non-prime attribute is functionally dependent on is a candidate key (unique attribute).



{DepNumber} -> DepName -> Mgr_ID

- Classes:

  In classes relation schema, there is a functional dependency on a non-prime attribute which is ClassRefNumber to other non-prime attributes which are Activity and InstructerID. Even though it is considered to be a transitive depency which is disallowed in third normal form, it is acceptable in this case because the non-prime attribute that the other non-prime attributes are functionally dependent on is a candidate key (unique attribute).



{Day,Hour,RoomNum] -> ClassRefNumber -> {Activity, InstructerID}

PART III: IMPLEMENTATION

6 Table Creation Script

In the following section, we will start creating all the tables for the smash up Gym data base, there are 14 tables, containing all the information of the gym's database.

6.1 *Employees* TABLE

In the create table command of the employees we added all the attributes that form the table and the primary key. Since it is the first table to be inserted in the database, after adding and creating all the other tables of the system, we will then add the foreign key constraints using the alter table command. We will do the same for the rest of the tables.

```
create table EMPLOYEES (
    EmpID numeric(10) primary key ,
    Fname varchar(31) ,
    Mname varchar(31) ,
    Lname varchar(31) ,
    DofBirth date not null,
    PhoneNo numeric(10) ,
    Gender char(1) ,
    Salary float(5) ,
    BankAccount numeric(15),
    City varchar(31),
    Street varchar(31) ,
    BuildingNumber varchar(31) ,
    DepNo numeric(2),
    BrNo numeric(3),
    check (Gender in ('F','M')));

Alter table EMPLOYEES
add constraint FK_DepNo foreign key (DepNo) references DEPARTMENTS(DepNumber) on
delete CASCADE  ;

Alter table EMPLOYEES
add constraint FK_BrNo foreign key (BrNo) references BRANCHES(BranchNumber) on delete
CASCADE ;
```

```
create table EMPLOYEES (
    EmpID numeric(10) primary key ,
    Fname varchar(31) ,
    Mname varchar(31) ,
    Lname varchar(31) ,
    DofBirth date not null,
    PhoneNo numeric(10) ,
    Gender char(1) ,
    Salary float(5) ,
    BankAccount numeric(15),
    City varchar(31),
    Street varchar(31) ,
    BuildingNumber varchar(31) ,
    DepNo numeric(2),
    BrNo numeric(3),
    check (Gender in ('F','M')));
```

```
Alter table EMPLOYEES
add constraint FK_DepNo foreign key (DepNo) references DEPARTMENTS(DepNumber) on delete CASCADE  ;

Alter table EMPLOYEES
add constraint FK_BrNo foreign key (BrNo) references BRANCHES(BranchNumber) on delete CASCADE ;
```

6.2 *Members* TABLE

```
create table MEMBERS (
    MemberID numeric(10) primary key ,
    Fname varchar(31) ,
    Mname varchar(31) ,
    Lname varchar(31) ,
    Email varchar(50) ,
    Gender char(1) ,
    DateOfBirth date not null,
    SocialState varchar(20),
    PhoneNumber numeric(10),
    BranchNo numeric(3),
   check (Gender in ('F','M')),
   check (SocialState in ('Single','Married')));

Alter table MEMBERS
add constraint FK_BranchNo foreign key (BranchNo) references BRANCHES(BranchNumber)on
delete CASCADE;

Alter table Members
add constraint CheckAge check ( DATEDIFF(Year , DateOfBirth,CURRENT_TIMESTAMP) >= 16)
```

```
create table MEMBERS (
    MemberID numeric(10) primary key ,
    Fname varchar(31) ,
    Mname varchar(31) ,
    Lname varchar(31) ,
    Email varchar(50) ,
    Gender char(1) ,
    DateOfBirth date not null,
    SocialState varchar(20),
    PhoneNumber numeric(10),
    BranchNo numeric(3),
   check (Gender in ('F','M')),
   check (SocialState in ('Single','Married')));
```

```
Alter table MEMBERS
add constraint FK_BranchNo foreign key (BranchNo) references BRANCHES(BranchNumber)on delete CASCADE;
```

```
Alter table Members
add constraint CheckAge check ( DATEDIFF(Year , DateOfBirth,CURRENT_TIMESTAMP) >= 16)
```

6.3 *Lockers* TABLE

```
create table LOCKERS (
LockerNo numeric(10) primary key,
Passwordd numeric(6) default 124567 ,
Statee varchar(20) not null default 'Available',
Owner_ID numeric(10) default null ,
BrNumber numeric(3) ,
check (Statee in('Occupied','Available'))
);

Alter table LOCKERS
add constraint FK_OwnerID foreign key (Owner_ID) references MEMBERS(MemberID) on
delete set default ;

Alter table LOCKERS
add constraint FK_BrNumber foreign key (BrNumber) references BRANCHES(BranchNumber);
```

```
create table LOCKERS (
LockerNo numeric(10) primary key,
Passwordd numeric(6) default 124567 ,
Statee varchar(20) not null default 'Available',
Owner_ID numeric(10) default null ,
BrNumber numeric(3) ,
check (Statee in('Occupied','Available'))
);
```

```
Alter table LOCKERS
add constraint FK_OwnerID foreign key (Owner_ID) references MEMBERS(MemberID) on delete set default ;

Alter table LOCKERS
add constraint FK_BrNumber foreign key (BrNumber) references BRANCHES(BranchNumber);
```

6.4 *Branches* TABLE

```
create table BRANCHES (
BranchNumber numeric(3) primary key,
City varchar(31),
Street varchar(20),
Building_No varchar(4),
PhoneNum numeric(10),
BranchCpacity numeric(3) not null,
Opening_Hours time(0)  not null,
Closing_Hours time(0) not null,
Manager_ID numeric(10));

Alter table BRANCHES
add constraint FK_ManagerID foreign key (Manager_ID) references EMPLOYEES(EmpID);
```

```
create table BRANCHES (
BranchNumber numeric(3) primary key,
City varchar(31),
Street varchar(20),
Building_No varchar(4),
PhoneNum numeric(10),
BranchCpacity numeric(3) not null,
Opening_Hours time(0)  not null,
Closing_Hours time(0) not null,
Manager_ID numeric(10));
```

```
Alter table BRANCHES
add constraint FK_ManagerID foreign key (Manager_ID) references EMPLOYEES(EmpID);
```

6.5 *Departments* TABLE

```
create table DEPARTMENTS (
DepNumber numeric(2) primary key,
DepName varchar(20),
Mgr_ID numeric(10),
Unique(DepName));

Alter table DEPARTMENTS
add constraint FK_MgrID foreign key (Mgr_ID) references EMPLOYEES(EmpID);
```

```
create table DEPARTMENTS (
DepNumber numeric(2) primary key,
DepName varchar(20),
Mgr_ID numeric(10),
Unique(DepName));
```

```
Alter table DEPARTMENTS
add constraint FK_MgrID foreign key (Mgr_ID) references EMPLOYEES(EmpID);
```

6.6 *Health records* TABLE

```
create table HealthRecords(
MemID numeric(10),
DateOfRecord date Not null,
BodyFat numeric(5,2),
BloodType char(3),
Weightt numeric(5,2),
Height numeric(5,2),
BMI numeric(5,2),
BodyWater numeric(5,2),
BloodPressure numeric(5,2),
MuscleMass numeric(5,2),
BodyMass numeric(5,2),
primary key(MemID,DateOfRecord), );

Alter table HEALTHRECORDS
add constraint FK_MemID foreign key (MemId) references MEMBERS(MemberID) on delete
CASCADE;
```

```
create table HealthRecords(
MemID numeric(10),
DateOfRecord date Not null,
BodyFat numeric(5,2),
BloodType char(3),
Weightt numeric(5,2),
Height numeric(5,2),
BMI numeric(5,2),
BodyWater numeric(5,2),
BloodPressure numeric(5,2),
MuscleMass numeric(5,2),
BodyMass numeric(5,2),
primary key(MemID,DateOfRecord), );
```

```
Alter table HEALTHRECORDS
add constraint FK_MemID foreign key (MemId) references MEMBERS(MemberID) on delete cascade ;
```

6.7 *Sports equipment* TABLE

```
create table SportsEquipment (
Machine_Number numeric(10) primary key,
MachineName varchar(31) ,
State varchar(31),
Bnum numeric(3) default 0,
check (State in('In Service','Out of service')));

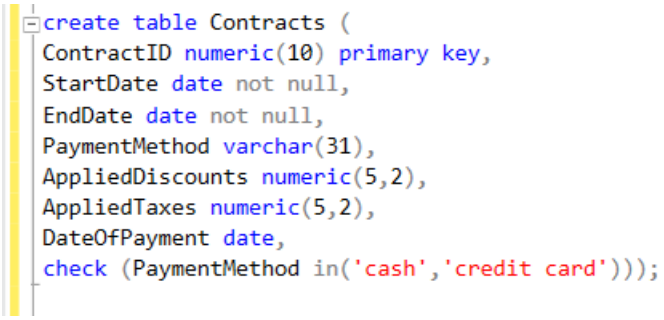
Alter table SportsEquipment
add constraint FK_BNum foreign key (BNum) references BRANCHES(BranchNumber) on delete
CASCADE;
```

```
create table SportsEquipment (
Machine_Number numeric(10) primary key,
MachineName varchar(31) ,
State varchar(31),
Bnum numeric(3) default 0,
check (State in('In Service','Out of service')));
```

```
Alter table SportsEquipment
add constraint FK_BNum foreign key (BNum) references BRANCHES(BranchNumber) on delete CASCADE;
```

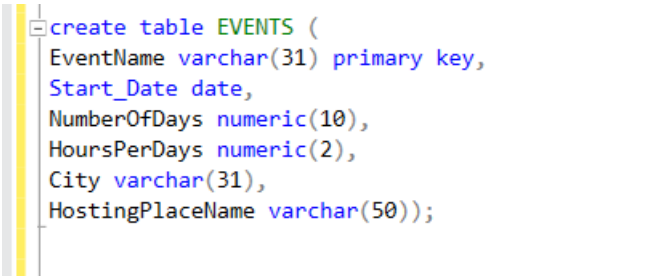
6.8 *Contracts* TABLE

```
create table Contracts (
ContractID numeric(10) primary key,
StartDate date not null,
EndDate date not null,
PaymentMethod varchar(31),
AppliedDiscounts numeric(5,2),
AppliedTaxes numeric(5,2),
DateOfPayment date,
check (PaymentMethod in('cash','credit card')));
```



6.9 *Events* TABLE

```
create table EVENTS (
EventName varchar(31) primary key,
Start_Date date,
NumberOfDays numeric(10),
HoursPerDays numeric(2),
City varchar(31),
HostingPlaceName varchar(50));
```



6.10 *Membership plans* TABLE

```
create table MembershipPlans (
MembershipPlanID numeric(10) primary key,
PlanName varchar(31),
Durationn varchar(31),
Price numeric(5),
check (PlanName in('Diamond','Golden','Platinum')),
check (Durationn in('3 months','6 months','12 months')));
```

```
create table MembershipPlans (
MembershipPlanID numeric(10) primary key,
PlanName varchar(31),
Durationn varchar(31),
Price numeric(5),
check (PlanName in('Diamond','Golden','Platinum')),
check (Durationn in('3 months','6 months','12 months')));
```

6.11 *Supervised_By* TABLE

```
create table Supervised_By(
EventName varchar(31) not null,
supervisorID numeric(10) ,
primary key(EventName , supervisorID));

Alter table Supervised_By
add constraint FK_EventName foreign key (EventName) references Events(EventName)on
delete CASCADE;

Alter table Supervised_By
add constraint FK_supervisorID foreign key (supervisorID) references
Employees(EmpID)on delete CASCADE;
```

```
create table Supervised_By(
EventName varchar(31) not null,
supervisorID numeric(10) ,
primary key(EventName , supervisorID));
```

```
Alter table Supervised_By
add constraint FK_EventName foreign key (EventName) references Events(EventName)on delete CASCADE;

Alter table Supervised_By
add constraint FK_supervisorID foreign key (supervisorID) references Employees(EmpID)on delete CASCADE;
```

6.12 *Services_Of_Plan* TABLE

```
create table Services_Of_Plan(
ServicesName varchar(31),
PlanID numeric(10),
primary key(ServicesName , PlanID));

Alter table Services_Of_Plan
add constraint FK_PlanID foreign key (PlanID) references
MembershipPlans(MembershipPlanID) on delete CASCADE;
```

```
create table Services_Of_Plan(
ServicesName varchar(31),
PlanID numeric(10),
primary key(ServicesName , PlanID));
```

```
Alter table Services_Of_Plan
add constraint FK_PlanID foreign key (PlanID) references MembershipPlans(MembershipPlanID) on delete CASCADE;
```

6.13 *Assigned_To* TABLE

```
create table Assigned_To(
MembershipID numeric(10),
ContractID numeric(10),
MemberID numeric(10),
TotalCost float(5),
primary key(MembershipID , ContractID , MemberID ));

Alter table Assigned_To
add constraint FK_MembershipID foreign key (MembershipID) references
MembershipPlans(MembershipPlanID) on delete CASCADE;

Alter table Assigned_To
add constraint FK_ContractID foreign key (ContractID) references Contracts(ContractID)
on delete CASCADE;

Alter table Assigned_To
add constraint FK_MemberID foreign key (MemberID) references Members(MemberID)on
delete CASCADE;
```

```
create table Assigned_To(
MembershipID numeric(10),
ContractID numeric(10),
MemberID numeric(10),
TotalCost float(5),
primary key(MembershipID , ContractID , MemberID ));
```

```
Alter table Assigned_To
add constraint FK_MembershipID foreign key (MembershipID) references MembershipPlans(MembershipPlanID) on delete CASCADE;

Alter table Assigned_To
add constraint FK_ContractID foreign key (ContractID) references Contracts(ContractID) on delete CASCADE;

Alter table Assigned_To
add constraint FK_MemberID foreign key (MemberID) references Members(MemberID)on delete CASCADE;
```

6.14 *Classes* TABLE

```
create table Classes(
Dayy varchar(31),
Hourr  time(0),
RoomNum  numeric(5),
ClassRefNumber numeric(10) unique,
Activity varchar(31),
InstructerID numeric(10),
primary key(Dayy , Hourr , RoomNum ));

Alter table Classes
add constraint FK_InstructerID foreign key (InstructerID) references EMPLOYEES(EmpID)
on delete CASCADE;
```

```
create table Classes(
Dayy varchar(31),
Hourr  time(0),
RoomNum  numeric(5),
ClassRefNumber numeric(10) unique,
Activity varchar(31),
InstructerID numeric(10),
primary key(Dayy , Hourr , RoomNum ));
```

```
Alter table Classes
add constraint FK_InstructerID foreign key (InstructerID) references EMPLOYEES(EmpID) on delete CASCADE;
```

7 Constraints Script

8	14	8
9	14	9
10	15	10

</td><td>Branches</td></tr>
</table>

To prevent overlapping, no two classes can occur at the same time, at the same room. So, we made the primary key a composite key made up of the combination of day, hour, and room number as heighted in the SQL script.	`create table Classes (` `Dayy varchar(31),` `Hourr  time(0),` `RoomNum  numeric(5),` `ClassRefNumber numeric(10) unique,` `Activity varchar(31),` `InstructerID numeric(10),` `primary key(Dayy , Hourr , RoomNum ));`	Classes Table

The device's state and location must be recorded, in case of an equipment that is out of service, the maintenance administrator responsible for a specific Branch will manually request to fix the devices.	``` create table SportsEquipment (…… …… …… State varchar(31), Bnum numeric(3) default 0, check (State in('In Service','Out of service'))); Select Machine_Number , MachineName ,State From SportsEquipment , BRANCHES Where BranchNumber=Bnum and Bnum =1 and state='Out of service' ```  Results Messages Machine_Number MachineName State 1 5000000003 Treadmill Out of service 2 5000000146 Leg Press Out of Service In case the device was fixed we must update its state to (In service). ``` update SportsEquipment set State='In service' where Bnum=1 and Machine_Number= 5000000003 ```  Results Messages Machine_Number MachineName State 1 5000000001 Treadmill In Service 2 5000000002 Treadmill In Service 3 5000000003 Treadmill In service 4 5000000037 Elliptical Machine In Service	Sports Equipment

Each branch must have several sports equipment, and an equipment must be located at a specific branch. To show this relation between branches and equipments, we added a foreign key that references the branches' number in the sports equipment table.	`Alter table SportsEquipment` `add constraint FK_BNum foreign key (BNum)` `references BRANCHES(BranchNumber);`	Sports Equipment

8 Queries and Transactions

8.1 *<Finding the minimum salary of employees>*

Query in Natural Language:

To evaluate and manage the gym's financial situation, we will use this query to help find the employees that get the least amount of salary out of all the employees of the gym, this query will display their IDs, full names, the department and the branch that they belong to and their salary amount.

SQL Script

```
select EmpID , Fname, Mname ,Lname , DepName,BrNo , Salary
from EMPLOYEES , DEPARTMENTS, Branches
where DepNo=DepNumber and BrNo=BranchNumber
and Salary =(select min(Salary)
             from EMPLOYEES)
```

Caption of the output:

8.2 <*Invoices* >

Query in Natural Language:

In section 1.4 we have said that one of our intended outputs of this system is generating an invoice once a member joins the gym and signs a contract deal for which membership plan they want to register, this generated invoice will display:

- Contract ID
- Member ID
- Plan's name
- Branch No
- Start date (Day, Month, Year)
- End date (Day, Month, Year)
- Date of payment (Day, Month, Year)
- Payment method (Cash/Credit card)
- Membership plan price
- Applied discounts
- Applied taxes
- Total cost

SQL Script:

```
select BranchNo, Fname ,Lname ,Contracts.ContractID ,
               Assigned_To.MemberID , PlanName,  StartDate , EndDate ,
               DateOfPayment ,PaymentMethod , Price , AppliedDiscounts ,
               AppliedTaxes , TotalCost
from   Contracts  , MEMBERS  , Assigned_To  , MembershipPlans
where  Contracts.ContractID = Assigned_To.ContractID
               and Assigned_To.MemberID= MEMBERS.MemberID
               and MembershipPlanID = MembershipID
               and DateOfPayment between '2022-05-15' and '2023-01-01'
order by BranchNo
```

8.3 <*Calculating the total profits of membership plans*>

Query in Natural Language:

To calculate the profits of every membership plan offered by our gym, we will use a query to help us count the total profits of each plan and how many members in our gym are registered in that plan. We will also benefit from this query to show which plan is most popular and profitable.

SQL Script:

```
select  PlanName,Durationn ,sum(TotalCost)as TotalProfits, count(*) as NumOfMembers
from Assigned_To,MembershipPlans
where MembershipID=MembershipPlanID
group by PlanName,Durationn
```

Caption of the First Five Rows of the Output:

8.4 *<Events schedule in a specific city>*

Query in Natural Language:

In order to see our plan of events in Jeddah for the year 2022 , we used a query to help and filter out only these events who were going to be hosted in Jeddah for 2022 , this query will not only display these events, but it will also display all of its information , like the place where it will be hosted and the supervisors IDs which will supervise these events, the duration of each event and so on. The schedule will be ordered in terms of the start dates of each event.

SQL Script:

```
select events.*,supervisorID
from events , Supervised_By
where events.EventName=Supervised_By.EventName and city IN('jeddah') and Start_Date
LIKE'2022-%%-%%'
order by Start_Date
```

Caption of the Output:

Query executed successfully.

8.5 <*Potential Qualified Blood Volunteers in each city*>

Query in Natural Language:

The National Blood Bank Center released an announcement for an open opportunity for donating with a few sets of conditions that the donators must fulfil, first the donator should be more than 20 years old with a weight range no less than 50 Kg. Since we want to urge our members to donate blood as it is very important, we used a query to help us calculate how many members belong to each specific blood type in each specific city. This query will filter out all the non-qualified members first and then calculate all the qualified members for each blood type.

SQL Script:

The query used for all the branches in Jeddah:

```
select BloodType ,  count(  Distinct MemberID) as NumOfmember
from HealthRecords , MEMBERS
where MemberID= MemID  and  memID = any (
                                        Select  MemberID
                                        from MEMBERS , BRANCHES
                                        where BranchNo=BranchNumber and DATEDIFF(Year
, DateOfBirth,CURRENT_TIMESTAMP) >20  and Weightt >=50 and  City='Jeddah'  )
group by  BloodType
```

The query used for all of the branches in Riyadh:

```
select BloodType ,  count(  Distinct MemberID) as NumOfmember
from HealthRecords , MEMBERS
where MemberID= MemID  and  memID = any (
                                        Select  MemberID
                                        from MEMBERS , BRANCHES
                                        where BranchNo=BranchNumber and DATEDIFF(Year
, DateOfBirth,CURRENT_TIMESTAMP) >20  and Weightt >=50 and  City='Riyadh'  )
group by  BloodType
```

Caption of the Output:

Query executed successfully.

8.8 <Deleting previous events>

Delete in Natural Language:

To organize the upcoming events schedule, we must check if an event has already been done so that we can delete it from the system's schedule. Therefore, we deleted the events that have already happened from the database by checking if their starting date has already passed. The date that we have checked the events was 2022-05-15. So all events in the past will be deleted.

SQL Script:

```
delete from EVENTS where Start_Date < CURRENT_TIMESTAMP
```

Caption of the Output:

Before deleting:

Results Messages

	EventName	Start_Date	NumberOfDays	HoursPerDays	City	HostingPlaceName
1	Boxing Competition	2022-03-04	2	3	Riyadh	Flagboxing

Since the events table is referenced by the Supervised_By table (which is responsible for stroing information about each event's supervisors) using the event's name ,this means that the events that have been deleted from the events table will cascade the deletion of all the rows that references the deleted event. Here is the Supervised_By table before and after deleting the events.

8.9 <Removing a specific member>

Delete in Natural Language:

Deleting a specific member by using its ID will cascade the deletion of all its health records in the system as well as it will return its locker's owner ID to be null.

SQL Script:

```
delete from MEMBERS where MemberID= 1000000001
```

Caption of the Output:

Since the owner' ID references the member ID, when deleting the ID that is equal to 1000000001of the members, the locker that had the owner ID equal to 1000000001 will also change its owner ID to become null as we wrote in the alter table statement. Since the owner ID has become null the state and password of the locker will remain the same. So we must update the lockers state and password to the default values set in the create table statements.

SQL Script:

```
update lockers
set Statee = default  , Passwordd= default
where LockerNo= 2000000001
```

Lockers table before deleting the member with ID = 1000000001:
